

Atypical Antipsychotics Step Therapy with Quantity Limit Program Summary

Step Therapy applies to FlexRx Open, FocusRx, GenRx Open, Health Insurance Marketplace, and KeyRx formularies.

This is a FlexRx Standard and GenRx Standard program.

The BCBS MN Step Therapy Supplement also applies to this program for all Commercial/HIM lines of business.

Quantity limits apply to FlexRx Closed, FlexRx Open, FocusRx, GenRx Closed, GenRx Open, Health Insurance Marketplace, and KeyRx.

CLINICAL RATIONALE

Schizophrenia	<p>Schizophrenia is a psychiatric disorder that involves chronic or recurrent psychosis. Antipsychotic medications are first-line treatment for schizophrenia. Antipsychotics have been shown to reduce positive symptoms of schizophrenia, such as hallucinations, delusions, and suspiciousness. Negative symptoms of schizophrenia, such as diminished emotional expression and lack of motivation, have proven particularly difficult to treat. Clozapine is generally considered the most effective antipsychotic drug for the treatment of schizophrenia. Due to adverse effects such as agranulocytosis and seizures, its use is reserved for patients with treatment-resistant disease, suicide risk, or risk of aggressive behavior despite other treatments. Antipsychotic medications are commonly grouped into two categories, with "second-generation" or "atypical" applied to clozapine and all antipsychotics first marketed after clozapine was approved in 1989, and "first-generation" applied to all antipsychotics marketed previously. Atypical antipsychotics tend to cause fewer extrapyramidal side effects than first generation antipsychotics. Elderly patients, in particular, are at increased risk of chronic confusion and disorientation during treatment with first generation antipsychotic drugs.(16,17)</p>
Bipolar Disorder	<p>Bipolar disorder is a mood disorder that is characterized by episodes of mania, hypomania, and major depression. Initiation of maintenance therapy is recommended to prevent relapse, minimize suicide attempts, and maybe associated with reduced rates of violent behavior. First line maintenance therapy is recommended, if possible, to consist of the same regimen that successfully treated the acute bipolar mood episode. Lithium, quetiapine, divalproex, and lamotrigine monotherapy are considered first-line treatments. Second line therapy is reserved for those who do not tolerate first-line maintenance pharmacotherapy. Olanzapine, risperidone, carbamazepine, paliperidone, ziprasidone, and lurasidone are all considered second-line therapies.(18,19)</p>

Major Depressive Disorder	Major depressive disorder (MDD), also known as unipolar major depression, is diagnosed when a patient has suffered at least one major depressive episode and have no history of mania or hypomania. Goal of initial treatment for depression is symptom remission and restoring baseline functioning. Selective serotonin reuptake inhibitors (SSRIs) along with serotonin norepinephrine reuptake inhibitors (SNRIs), bupropion, and mirtazapine are considered first line treatment options for adults with major depressive disorder (MDD). Guidelines do not consider antipsychotics as a first line treatment of major depressive disorder without psychosis. However, they suggest that psychotic depression typically responds better to the combination of an antipsychotic and an antidepressant medication rather than either component alone, although some research has shown comparable responses for anti-depressive treatment or antipsychotic treatment alone.(20,21)
Autism	<p>Practice Parameters-American Academy of Child and Adolescent Psychiatry (AACAP, 2014) suggest pharmacotherapy may be offered when there is a specific target symptom or comorbid condition, potentially increasing patient ability to profit from educational and other interventions, and allow less restrictive environments through management of severe and challenging behaviors. Frequent targets for pharmacologic intervention include associated comorbid conditions (e.g., anxiety, depression) and other features (e.g., aggression, self-injurious behavior, hyperactivity, inattention, compulsive-like behaviors, repetitive or stereotypic behaviors, and sleep disturbances). Various considerations (e.g., adverse effects) should inform pharmacologic treatment. Risperidone and aripiprazole have been FDA approved for the treatment of irritability (e.g., physical aggression, severe tantrum behavior) associated with autism. There is a growing body of controlled evidence for pharmacologic intervention. The guideline provides a summary chart of medications supported by RCTs for use in children with autism spectrum disorder (ASD), including target symptoms, ages, dosing, potential adverse effects, and outcomes.</p> <ul style="list-style-type: none"> ▪ Antipsychotics supported by RCTs showing positive effects on various target symptoms in ASD include aripiprazole, haloperidol, olanzapine, and risperidone. ▪ Combining medication with parent training is moderately more efficacious than medication alone for decreasing serious behavioral disturbance and modestly more efficacious for adaptive functioning. Individuals with ASD may be nonverbal, so treatment response is often judged by caregiver report and observation of specific behaviors. Although this may help document the effectiveness of the selected medication, an overall goal of treatment is to facilitate the child’s adjustment and engagement with educational intervention. <p>Despite many randomized trials, confidence in reported improvements remains low for most interventions. Risperidone and aripiprazole improved challenging behavior in the short term (less than 6 months) but also significant harms including weight gain, appetite changes, and EPS.(22,23)</p>
Dementia-Related Psychosis (off-label use)	<p>The American Psychiatric Association (APA) recommends that nonpharmacologic interventions be attempted before a trial of antipsychotic drug therapy and that the interventions attempted be guided by the patient’s level of distress and the risk to the patients and caregiver. In addition, the FDA states that physicians who prescribe antipsychotics to elderly patients with dementia-related psychosis should discuss the risk of increased mortality with their patients, patients’ families, and caregivers. Evidence indicates that antipsychotics provide weak benefits for the treatment of psychosis and agitation in patients with dementia. Adverse effects of antipsychotics include sedation, metabolic effects, and cognitive impairment. For many patients with Alzheimer’s disease, antipsychotics can be tapered and discontinued without significant signs of withdrawal or return of behavioral symptoms.</p> <p>Antipsychotic drug therapy generally is reserved for patients who have severe symptoms or when associated agitation, combativeness, or violent behavior puts the patient or others in danger. Current evidence indicates that the atypical antipsychotics can provide modest improvement in behavioral manifestations; some evidence suggests that efficacy may be better for psychosis than for other manifestations. Antipsychotic efficacy appears to be similar among available agents and therefore the</p>

	<p>choice of agent should be based on adverse effect profile and other patient considerations; to minimize adverse effects, the lowest possible effective dose should be used.(24,25)</p>
<p>Tourette's Disorder</p>	<p>Tourette's disorder is a neuropsychiatric disorder characterized by involuntary motor and vocal tics. Although the etiology of Tourette's disorder is unknown, evidence suggests that pathophysiology of this disorder involves an abnormality in the central dopaminergic system. Currently, the medications that are FDA approved for the treatment of Tourette's disorder are aripiprazole, haloperidol, and pimozide although most clinicians use atypical antipsychotics prior to the two approved agents. Clonidine and guanfacine are considered first line agents due to their low side effect profile. However, the level of evidence for their effectiveness is less than antipsychotics and they lack an FDA approval. Atypical neuroleptics (aripiprazole or risperidone) are typically used if the alpha-2 agonists are ineffective or intolerable.</p> <p>According to the American Academy of Neurology guidelines, there was moderate confidence that haloperidol, risperidone, aripiprazole, tiapride, clonidine, onabotulinumtoxin A injections were probably more likely than placebo to reduce tics. There was low confidence that pimozide, ziprasidone, metoclopramide, guanfacine, topiramate, and tetrahydrocannabinol were possibly more likely than placebo to reduce tics. There is high confidence that the patients need to be counseled and monitored for adverse events such as weight gain, drug-induced movement disorders, elevated prolactin levels, sedation, and effects on the heart rate, blood pressure, and ECGs. The class of medicine is selected based on the severity of the tics and the side effect profile of the medicine based on other comorbidities such as depression, anxiety, and sleep disturbance. The American Academy of Child & Adolescent Psychiatry states that atypical antipsychotics are effective in Tourette's Disorder (TD). At the time the guidelines were published, no atypical antipsychotics were FDA approved, and only haloperidol and pimozide had been approved for TD. The guidelines found that risperidone is the most well studied non-FDA labeled atypical antipsychotic for the treatment of TD. Risperidone was found to be at least as effective as clonidine, haloperidol, and pimozide; with less frequent and severe side effects. The most common adverse reaction with risperidone therapy was mild to moderate sedation. No clinically significant extrapyramidal symptoms were observed.(26-29)</p>
<p>Safety</p>	<p>The atypical antipsychotic agents carry a boxed warning for increased mortality in elderly patients with dementia-related psychosis. The warning states that elderly patients with dementia-related psychosis treated with antipsychotic drugs are at an increased risk of death. These agents are not approved for the treatment of patients with dementia-related psychosis.(1-15,30-33)</p> <p>Abilify, Caplyta, Latuda, Rexulti, Risperdal, and Seroquel/Seroquel XR have an additional boxed warning for an increased risk of suicidal thoughts and behaviors in pediatric and young adult patients. Closely monitor all antidepressant-treated patients for worsening and emergence of suicidal thoughts and behaviors.(2,4,6,8,11,14,30,32)</p> <p>All clozapine agents including Versacloz, have the following boxed warnings:(1,12,13)</p> <ul style="list-style-type: none"> • Severe Neutropenia: Clozaril can cause severe neutropenia, which can lead to serious and fatal infections. Patients initiating and continuing treatment with Clozaril must have a baseline blood absolute neutrophil count (ANC) measured before treatment initiation and regular ANC monitoring during treatment. • Clozaril is available only through a restricted program called the Clozapine Risk Evaluation and Mitigation Strategy (REMS). • Orthostatic Hypotension, Bradycardia, and Syncope: Risk is dose related. Starting dose is 12.5 mg. Titrate gradually and use divided dosages. • Seizure: Risk is dose related. Titrate gradually and use divided doses. Use with caution in patients with history of seizure or risk factors for seizure. • Myocarditis, Cardiomyopathy and Mitral Valve Incompetence: Can be fatal. Discontinue and obtain cardiac evaluation if findings suggest these cardiac reactions.

- Increased Mortality in Elderly Patients with Dementia-Related Psychosis: Clozaril is not approved for this condition.
